# The Human Genome

BIOL3120 Human Genetics and Evolutionary Medicine

The Human Genome

LEARNING OBJECTIVES

At the end of this lecture you should be able to:

- Define the terms used to describe the human genome

- Understand the structure of chromosomes

- Understand the coding regions of the human genome

The human genome

- First draft sequence February 2001
- Complete draft 2003
- Cost ~ 2.7 billion USD

Cost per Genome

The human genome

- First draft sequence February 2001
- Complete draft 2003
- Cost ~ 2.7 billion USD

- Sequence determined but little understanding of its meaning

Quick overview

- 3.2 billion basepairs x 2

- Over 23 chromosome pairs

- ~20,000 protein-coding genes

Exons (1.5%)

Regulatory sequences (5%)

Introns (~20%)

Repetitive DNA that includes transposable elements and related sequences (44%)

L1 sequences (17%)

Unique noncoding DNA (15%)

Repetitive DNA unrelated to transposable elements (14%)

Alu elements (10%)

Simple sequence DNA (3%)
Large-segment duplications (5–6%)

Junk DNA?

- Historically, non-coding DNA referred to as junk DNA

- ENCODE project (2012):
    - "The vast majority (80.4%) of the human genome participates in at least one biochemical RNA- and/or chromatin-associated event in at least one cell type"
    - (think about gene definition)

# Terms used to describe the human genome

Chromosomes

Chromosome related nomenclature

- Chromatin: the material of which chromosomes are made.
  - complex of DNA, and proteins (histones and non-histones)

- Chromatid: one of the two copies of a chromosome
  - joined at the centromere
  - two homologous chromatids are called sister chromatids.

- Centromere is DNA normally in a heterochromatin state
  - Site of spindle attachment to chromosomes (important in meiosis)

CHROMOSOME

CENTROMERE

CHROMATID   CHROMATID
# Chromosome parts

- Heterochromatin:
  - More condensed
  - Silenced genes (methylated)
  - Gene poor (high AT content)
  - Stains darker
- Euchromatin:
  - Less condensed
  - Gene expressing
  - Gene rich (higher GC content)
  - Stains lighter
DNA & Gene parts

- Enhancers: genomic DNA (gDNA) which can alter the expression of a gene
- Promoters: gDNA region where transcription factors bind to initiate transcription of a gene
- Exons: gDNA that is the coding regions of a gene
- Introns: a portion of a gene that does not code for an amino acid
- Gene: a sequence of nucleotides in DNA that codes for a molecule that has a function
The Structure of Chromosomes

Chromosome numbering

- 1-22 Arranged in order of decreasing size

- q = long arm; p = short arm
G-banding example: Chromosome 4
- Giemsa stain
  - darker on heterochromatin (AT rich) regions, less accessible
  - Lighter on euchromatin (GC rich) regions, more accessible and active
  - 92% of genes in euchromatin in humans

Chromosome numbering

- 1-22 Arranged in order of decreasing size

- q = long arm; p = short arm

- Black and white stripes are because of staining: G-banding

- 'Bands' have the same appearance on homologous chromosomes so identification became easier

- Banding allows:
  - Unequivocal identification of each human chromosome
  - Detection of rearrangements (e.g. translocations)
Chromosomes

Telomeres

- protect functional regions (containing genes) by capping the ends with a 'buffer' sequence
- Telomeres consist of variable numbers of a repetitive sequence (TTAGGG)
- Telomere length is reduced every time a cell divides
- average telomere length declines from ~ 11 kilobases at birth to less than 4 kilobases in old age, decline greater in men
- Marker of cell age – signal for apoptosis (cell self-destruction)
- **"telomeric** DNA is **lost** at an **average rate** of '25.7–27.7 base pairs' per year
Telomeres

- Various premature ageing disease characterised by critically short telomeres

- Cancer cells often do not show telomere length shortening - telomerase protein not normally active has become active in many cancer cell types

- Telomerase and telomere-binding proteins are potential targets for anti-cancer and anti-ageing therapies

LONG TELOMERES   SHORT TELOMERES

Telomere DNA Cell Cream
Net WT. 1 Oz. (30g)

Pseudoautosomal regions on X & Y chromosomes

- Homologous regions at ends of X and Y chromosomes

  - Allows pairing during meiosis
  - Regions tend not to be silenced in X-inactivation
  - Inherited in an autosomal manner
  - These regions are called PAR1 and PAR2
Number of genes on each chromosome

| Chromosome	Length (mm)	Base pairs	Variations	Protein-coding genes	Pseudo-genes	Total long ncRNA	Total small ncRNA	miRNA	rRNA	snRNA	snoRNA	Misc ncRNA	Links	Centromere position (Mbp)	Cumulative (%)

https://en.wikipedia.org/wiki/Human_genome
Gene size in humans

- Titin gene (TTN)
  - 365,719bp total gene size (including introns)
  - Exons: 80,781bp across 365 exons

- DMD gene (Duchenne muscular dystrophy)
  - 2,220,390 bp including introns
  - ~14kb mRNA

- Average gene size ~8kb
Coding Regions Human Genome

Human genome summary

- 3.2 billion base pairs x 2 across 23 chromosome pairs
- ~20,000 protein coding genes, but other functional molecules
- Only 1-2% codes for protein, but up to 80% of genome regulatory function
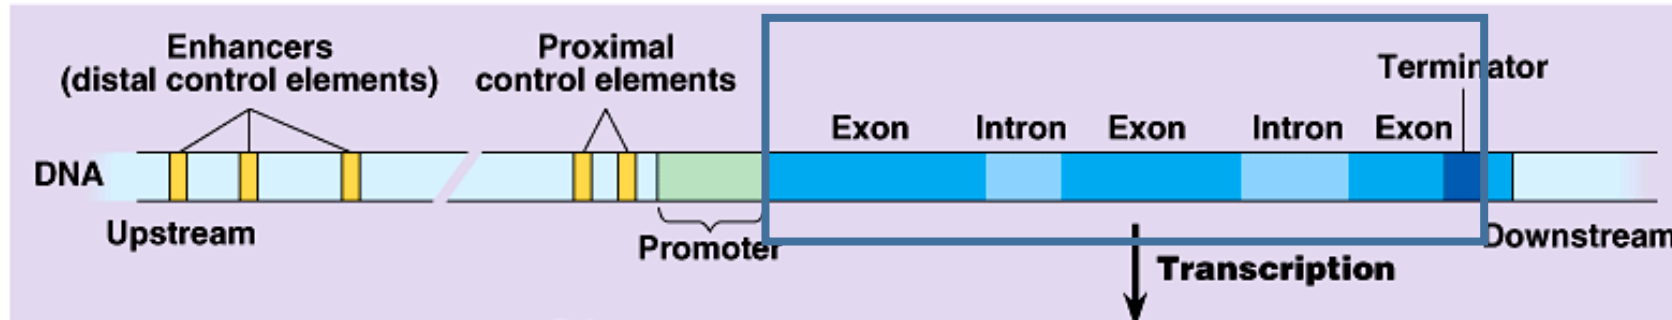

How many genes?

What is a gene?

- Classically, region of DNA which codes for a protein

- Nowadays:
  - a sequence of nucleotides in DNA that codes for a molecule that has a function
  - This might code for a protein, or just be transcribed into RNA e.g. t-RNAs, non-coding RNAs
What is a gene?

Copyright © Pearson Education, Inc., publishing as Benjamin Cummings.

Exons and introns

- Exon: part of a gene that will encode a part of the final mature RNA

- Intron: any nucleotide sequence within a gene that is removed by RNA splicing during maturation of the final RNA product

- 1.1% of the genome is spanned by exons, whereas 24% is in introns, with 75% of the genome being intergenic DNA

Multiple transcripts / alternate splicing

- Exons can be alternatively arranged to create different proteins from the same gene

- Different types of cells often use different transcripts more/less frequently

The Human Genome

LEARNING OBJECTIVES

At the end of this lecture you should be able to:

- Define the terms used to describe the human genome

- Understand the structure of chromosomes

- Understand the coding regions of the human genome
